On the right, click the Install button if it is not installed, then click Open.-type="fig"}), the presence of the arginine clusters is not affected by the presence of the magnesium. It would be interesting to further investigate the stability of the protein-DNA complexes and how the magnesium or the arginine clusters influence the DNA conformation. The results presented here show that combining the two features in one structure, the arginine cluster motif and the magnesium stabilisation, is able to enhance the binding affinity. Conclusions ===== This study has shown that the Arg clusters, as conserved functionalities of the VAV protein family, have the ability to bind DNA, with higher affinity than a sequence-based consensus motif, and the same affinity as a non-consensus-based consensus. The positively charged arginine clusters improve the affinities of the DNA binding through additional salt bridges and hydrogen bonds. We also show that the binding affinity of the VAV protein is significantly enhanced by magnesium stabilisation. It is important to note that arginine clusters are conserved in all VAV proteins. Therefore, our results show that, for a protein to function effectively, the arginine clusters have to be present on the surface of the protein. We hypothesise that the high binding affinities observed for the arginine clusters could be due to the relatively wide distribution of the clusters across the protein surface, which are potential candidate binding sites. These results also suggest that other protein families with high sequence variability but conserved arginine clusters could have high binding affinities.
